Abstract
Background: Breast feeding (BF) is known to have many advantages but our Arab region has a pattern similar to western countries; where exclusive breastfeeding less than 35%. Knowledge given to women during her antenatal visits plays an important influential role in her attitude and practice of BF later on.

Objective: To explore knowledge and attitude of female medical students at Taibah University about breastfeeding.

Methods: A Cross sectional survey was carried out from October through November 2012. It included female medical students. Proportional sampling allocation technique was used; with a total sample of 149 students. A specialty designed self-administrated questionnaire in Arabic form was used. It included socio-demographic data, obstetric history, data about the knowledge and attitude of female medical students towards breastfeeding value and guidelines. Mean percent knowledge score for value of BF, mean percent score for BF guidelines and mean percent score for attitude were calculated. Appropriate statistical tests for qualitative and quantitative data were used accordingly.

Results: Majority (91.9%) was never married and 37.6% got their knowledge about BF via books. Regarding ever married women, 58.3% only were gravid (mean =2.2±1.94). Only 25.0% were family planning users; 66.7% of them used hormonal contraceptives. Only 20% breast fed their infants with a mean duration for exclusive BF of 3.8 ± 2.87 months and mean age of weaning of 2.3 ±0.63 months. The mean knowledge percent score for guidelines of BF was 64.7±8.45. The mean attitude percent score for concepts related to BF was 76.9±7.91.

Conclusion: Media and internet have minor roles in getting knowledge about BF. The mean knowledge score about advantages of BF, guidelines of BF and attitude towards BF of all female medical students; especially academic years were unsatisfactory.

Key Words
Breastfeeding; Knowledge; Attitude; Medical students; Females; Exclusive breastfeeding; Weaning.

Introduction
Breastfeeding is the healthiest form of feeding for babies. In addition to its strengthening maternal infant bond, breastfeeding (BF) significantly decreases a lot of infant’ morbidities accompanying consumption of artificial feeding.1 Breastfeeding results in protection of infants; with a variable proportions against many diseases as acute respiratory infections2, type I diabetes3, otitis media.4,5 Exclusively breast-fed infants for six months were able to crawl earlier and start to walk at about age of one year.6

Breastfeeding has many benefits for nursing mothers as well as their newborn. It is easy; needs no preparation, economic, enhancing involution of uterus and has contraceptive effect by suppressing the ovulation process, which is known as “lactation amenorrhrea”.7,8 Two Honduran studies suggested that exclusive breastfeeding for six months was associated with delayed recommencement of menses and rapid regaining of pre-pregnancy weight.9 BF is also associated with other health benefits to women such as decreased risk of breast and ovarian cancers.10 Breast feeding (BF) is known to have many advantages but our Arab region has a pattern similar to western countries; where exclusive breastfeeding less than 35% (12% in Qatar, Kuwait; 31% in Oman; 31% in Saudi Arabia and 34% in Bahrain and the UAE).11 Knowledge given to women during her antenatal visits plays an important influential role in her attitude and practice of BF later on. Perception
of physicians as well is a crucial factor in increasing
the breastfeeding practice.

Assessment of physicians’ perception of BF, therefore; is important starting point to improve BF
practice as they are the key persons and first line
who instruct, motivate and follow mother to
correct BF practice. Hence this study was carried
out.

Objective
To explore knowledge and attitude of female
medical students (who will be the future physicians)
at Taibah University about breastfeeding.

Subjects and Methods
A Cross sectional study was carried out from
October through November 2012. The study was
carried out at female section, Medical college,
Taibah University, Al-Madinah. It included female
medical students in both academic (first and second
years) and clinical years (third to fifth years).
Stratified sampling technique with proportional
allocation was used; where the students were
divided into strata according to their level. Then
according to the number of students at strata 50%
of them were included; with a total sample of 149
students. A specially designed self-administrated
questionnaire in Arabic form was used. It included
socio-demographic data (age, level, marital status),
obstetric history for ever married students
(gravidity, parity, abortion, family planning,
breastfeeding practice), data about the knowledge
and attitude about breastfeeding -values, guidelines
and concepts. Readability of the questions was
assessed using Cronbachs alpha (0.862). Pilot study
on 20 students was carried out to refine the
questionnaire.

Approval of the Medical College Research
Committee was considered. Both verbal and
written consents of all participants were obtained;

*Pearson’s Chi-square test, ¥Fishers’ Exact test, ^ students’ t test, p- value is significant at < 0.05

Table 1: General description of the studied students by grade
before inclusion and after explanation of the
objectives of the study. Confidentiality and privacy
of the participants were assured.

Percent knowledge score for the following: value of
BF, percent score for BF guidelines and percent
score for attitude were calculated using the
following formula:

\[ \text{Percent score} = \frac{\sum \text{Selected variables scores}}{\text{Maximum possible score}} \times 100 \]

Statistical analysis
SPSS package version 17 was used. Frequencies,
percentages, proportions, mean and standard
deviation were calculated. Chi square test, Fisher’s
Exact test and student’s t-test were used accordingly.
P-value was considered significant at level less than
0.05 level.

Results
The mean age of the studied students was 21.0 ±
1.41 years; with significant difference between
academic and clinical years (P=0.000). The majority
(91.9%) was never married and 37.6% got their
knowledge about BF via books (Table 1).
Regarding ever married women, 58.3% only were gravid (mean=2.2±1.94); with insignificant difference between academic and clinical years. Only 20% of ever married, ever gravid students breast-fed their infants (Figure 1) with a mean duration for exclusive BF of 3.8 ± 2.87 months and mean age of weaning of 2.3 ±0.63 months; with insignificant difference between academic and clinical years. (Data were not presented). Only 25.0% of them were family planning users; 66.7% of them used hormonal contraceptives; with insignificant difference between academic and clinical years (Figure 1 and 2).

The mean knowledge percent score for advantages of BF was 67.2 ±9.58; with insignificant difference between academic and clinical years. The highest percent was for value of BF (99.3%) followed by value of colostrum (97.3%) (Table 2).

The mean knowledge percent score for guidelines of BF was 64.7±8.45; with insignificant difference between academic and clinical years (Table 3). Nevertheless, the mean attitude percent score for concepts related to BF was 76.9±7.91; with insignificant difference between academic and clinical years (Table 4).

**Discussion**

The most excellent first foodstuff for newborn is breast milk. The present work revealed that the mean knowledge score (unfortunately for female medical students) for advantages of BF was (67.2±9.58), and its guidelines was (64.7±8.45),
which were unsatisfactory. The Medical Education System in the medical College should pay attention for this pitfall; as these students will be the crucial persons who will disseminate the knowledge about BF.

The present work revealed that only 20% of studied highly educated medical students practicing BF; for a very short duration (3.8±2.87 months) and early weaning (2.3±0.63 months). Although many benefits have been stated for breastfeeding, its practice is still lower than that recommended by WHO. High prevalence of unhygienic bottle feeding; especially by illiterate mothers increases infant mortality.12,13

The last 20-30 years, Saudi Arabia had many socioeconomic changes which introduced many foreign unpopular norms, many of which have influenced its population and changed their habits. There is a trend toward bottle feeding both in urban and rural areas.14 Before that it is believed that BF was very common and in some cases it may exceed two years, as all the populations in the kingdom are Muslims nursing mothers are expected to follow the Holy Koran, which instructs them to breastfeed their children for up to two years.12

*Pearson’s Chi-square test, ¥Fishers’ Exact test, ^ students’ t test, p-value is significant at < 0.05

**Table 4:** Students’ attitude about some concepts related to BF by grade
In Saudi Arabia, a national health survey reported that the initial prevalence of breastfeeding (BF) was 90%, becoming 50% at three months and dropping down to 10% at one year. Another survey, which included eleven primary health care centers, found that only 21.5% were exclusively breastfeeding, 20.6% artificially fed, and 57.9% had a combination of both breastfeeding and artificial feeding.

A considerable number of both community and hospital-based studies have carried out in Saudi Arabia looking at infant feeding practices. Most has shown that BF in the country is less than optimal. In 1994, the first six months of breastfeeding were exclusive in only 31% despite its known benefits. A considerable number of both community and hospital-based studies have carried out in Saudi Arabia looking at infant feeding practices. Most has shown that BF in the country is less than optimal. In 1994, the first six months of breastfeeding were exclusive in only 31%. One study in King Khalid University hospital in 1985 showed that 51% of the mothers began weaning at 6-12 months. In the kingdom, baby-friendly hospital initiative (BFHI) activities were started in 1992 and BFHI training was started in 1995 with technical and material assistance from WHO. Then the activities of BFHI have been extended from hospitals to health centers and communities, with the health friends committees functioning as community support teams for promoting breastfeeding BF.

The present work showed that the attitude score of the surveyed students towards some basic concepts of BF was fair (76.9±7.9). They obtain their knowledge from books, internet, media and friends. Care must be paid to the information given by these sources as they are influential. Causes for discontinuation of breastfeeding as stated by Saudi women include insufficient breast milk, new pregnancy, use of inappropriate hormonal contraceptive method, maternal age, educational level, parity, family income, place and mode of delivery.

Staff training has special importance, particularly for health care workers who are directly responsible for mothers ‘caring giving them consistent information on appropriate infant feeding. They should be aware with method of BF, psychosocial factors and probable difficulties and how to deal with them. Knowledge alone is inadequate; staff necessitate positive attitude gained by experience. They are in a big need to understand the great benefits that gained for both nursing mothers and infants if follow this feeding pattern.

Conclusion

Media and internet have minor roles in getting knowledge about BF. The mean knowledge score about advantages of BF, guidelines of BF and attitude towards BF of all female medical students; especially academic years were unsatisfactory.

Recommendation

There is urgent need to strengthen the role of media and interne in disseminating knowledge about BF targeting medical students. Emphasis must be done for advantages of BF, guidelines and enhancing attitude towards BF practice. Further intervention researches are needed to study pre and post-study effects of health education knowledge, attitude and practices (KAP) effects.

Study limitations

The cross sectional design of the study did not allow measurement of the actual future practice of BF. Inclusion of all students will be needed in further studies. The number of the included married students; who actually constituted a low percent of the students (and we try to include all of them), was a weak point in this research.
