Abstract
Background: Bevacizumab is a monoclonal antibody that binds to all kinds of vascular endothelial growth factor (VEGF) and is successfully used as a systemic drug in treatment of cancers. Several previous studies have revealed the usefulness of the intravitreal injection of bevacizumab in treatment neovascularization and macular edema secondary to several eye diseases.

Purpose: To point out the indications and assess short-term outcome of bevacizumab intravitreal injection at Regional Referred Eye Hospital in Madinah Area, Saudi Arabia.

Methods: The study included 59 eyes of the studied patients submitted to intravitreal injection of bevacizumab at Regional Referred Eye Hospital in Madinah Area, Saudi Arabia, during the period from June to December 2015. At baseline, visual acuity and optical coherence tomography (OCT) were measured and data sheet was filled for each studied patient. The outcome variables in terms OCT thickness in micrometers and visual acuity were measured three months after injection. The data were analyzed by appropriate statistical tests.

Results: Of the 59 studied eyes, the majority 35 (59.3%) were diagnosed as diabetic macular edema (DME), 9 (15.3%) as proliferative diabetic retinopathy (PDR), 5 (8.5%) as combined PDR and vitreous hemorrhage (VH), 4 (6.8%) as combined DME and PDR, 2 (3.4%) as choroidal neovascularization (CNV) secondary to age-related macular degeneration, 2 (3.4%) as macular edema secondary to central retinal vein occlusion (CRVO), 1 (1.7%) as macular edema secondary to branch retinal vein occlusion (BRVO) and 1 (1.7%) as neovascular glaucoma. Compared to baseline mean OCT thickness, there was a statistically significant decrease in mean OCT thickness measured three months after injection. It was markedly decreased in patients aged ≤ 60 years (54.2%), male patients (37.2%), type II diabetics (52.5), best corrected visual acuity of ≥ 0.1 (45.7%), non-hypertensive (42.3%), and those with DME (38.9%), PDR (8.4%), with PDR and VH (8.4%) and those with DME and PDR (6.7%) more than 10% Moreover, the visual acuity was improved in 9 (43%) out of 21 eyes with baseline visual acuity < 0.1 Decimal.

Conclusions: Diabetic macular edema was the commonest indication followed by proliferative diabetic retinopathy. In addition, the study confirms the accumulating evidence of the usefulness and short-term efficacy of intravitreal injection of bevacizumab. The study suggests the need for further investigations with larger multicenter randomized studies in our region and a longer follow up to verify if this improvement is sustainable or not. However, the major concern is the need for increasing awareness about the importance of diabetes control and its impact in our region.

Introduction
Bevacizumab is a monoclonal antibody that binds to all kinds of vascular endothelial growth factor (VEGF) and is successfully used as a systemic drug in the treatment of cancers. VEGF is known to have a pivotal role in the process of neovascularization and increasing vascular permeability in diabetic eyes. Apart from laser photoocoagulation, which is the primary treatment modality, intravitreal injection of bevacizumab was used widely in treatment of various types of macular edema. Several previous studies have revealed the usefulness of the procedure in decreasing macular edema secondary to central retinal vein occlusion, fibrovascular proliferation secondary to proliferative diabetic retinopathy (PDR), and choroidal neovascularization (CNV) secondary to age-related macular
degeneration and secondary to vogt-koyanagi-harada syndrome (VKH)\(^1\)\(^{-12}\).

In animal studies, no toxicity was noted following intravitreal bevacizumab injection in albino rabbit retina at different concentrations up to 2.5 mg\(^1\). In human studies, however, some rare systemic and ocular complications have been reported. The systemic complication included increase in blood pressure, followed by cerebrovascular accidents and myocardial infarction\(^1\). Endophthalmitis, a severe ocular complication, was also reported in previous studies\(^{11-13}\). The prognostic value of patients' characteristics such as age, gender, and best-corrected visual acuity (BCVA) at baseline were analyzed in other studies\(^{14-18}\). These studies identified young age, male gender, and good BCVA at baseline as favorable prognostic factors.

Although the wide indications of use of intravitreal bevacizumab injections, in the Saudi literature there was no overall collective indications of the usefulness of this intravitreal drug for variety indications. From this point of view, the present study aimed to point out the collective and frequent indications of intravitreal bevacizumab and assessing the short-term outcome of patients treated with intravitreal Bevacizumab injections at the regional referred eye Hospital in Madinah Area, Saudi Arabia.

Methods

The present follow up study included 59 eyes of the studied patients submitted to intravitreal injection of bevacizumab at regional referred Eye Center of Ohoud Hospital in Madinah Area, Saudi Arabia during the period from June to December 2015. All patients who met the inclusion criteria at Eye Center of Ohoud Hospital of both genders came for their first intravitreal bevacizumab injection and aged more than 18 years were eligible for the study. The exclusion criteria included, patients who were mentally not able to give consent and those refused to participate were excluded from the study. An Official Publication of the Education and Research Division of Doctors Academy

The visual acuity and optical coherence tomography (OCT) were measured and data sheet was filled at the baseline (one week before bevacizumab injection). OCT was done on Topcon 3D OCT 2000(picture angle 45 degrees with an in-depth resolution of 5 micrometer) prior to procedure using the Cirrus HD-OCT device to assess the macular thickness. Intravitreal injection of 1.25 mg/0.05ml of bevacizumab was injected 3.5-4mm from limbus under local anesthesia by the Doctor in charge. Post procedure OCT was done on all studied patients three months after injection and the final outcome was determined on the basis of macular thickness in micrometers. Visual acuity was also measured.

DME was defined as retinal edema or hard exudates within 500 micrometers of the center of macula, retinal edema one disc diameter or larger, any part of which was within one disc diameter of center of macula as evaluated on OCT\(^20\).

All data analyses were done using statistical analysis system (SAS) software package\(^21\). The data were presented as mean ± SD for continuous variables and frequencies and percentages for categorical variables. The mean OCT diameters were compared before and after bevacizumab injections using paired t test. In order to compare the percent reduction in the thickness of OCT, three months following injection of bevacizumab, among the studied patients, chi square, Fischer exact and McNemar tests were used as appropriate. P value ≤ 0.05 was considered as an indicator of statistically significant difference. Ethical consideration was taken to ensure the confidentiality and privacy of the collected data. Written consent was taken from all studied patients. Patients who were mentally not able to give consent and those refused to participate were excluded from the study. Deanship of Scientific Research Ethics Committee at Tabah University, Madinah, Saudi Arabia, approved the study protocol.

Results

The study analyzed data from 59 eyes of the studied patients. The mean age of the patients was 56.7 ± 10.9 years, of them 78% were ≤ 60 years old. More than one half of them (55.9%) were male. The majority of the studied patients (79.7%) were type II diabetic patients. Less than half of patients were hypertensive (39%). Of the studied subjects the majority, 35 eyes (59.3%) were diagnosed as diabetic macular edema (DME), 9 eyes (15.3%) as proliferative diabetic retinopathy (PDR), 5 eyes (8.5%) as combined DME and PDR, 2 eyes (3.4%) as choroidal neovascularization (CNV) secondary to age-related macular degeneration (ARMD), 2 eyes (3.4%) as macular edema secondary to central retinal vein occlusion (CRVO), 1 eye (1.7%) as macular edema secondary to branch retinal vein occlusion (BRVO) and 1 eye (1.7%) as neovascular glaucoma. The mean OCT macular thickness for all studied patients at their baseline was 425.2 ± 168.9 micrometers. Also, the baseline of best corrected visual acuity (≥ 0.1 Decimal) was found in 64.4% of the studied patients (Table 1).

*Data are presented by mean ± SD or by n (%).

**Table 1:** Characteristics of Studied Patients
Table 2 compared the mean OCT thickness of the studied patients before and after Bevacizumab injection by their characteristics. Statistically significant difference was detected between the mean OCT thickness before and after injection among all studied patients (p=0.04). Also, a significant reduction in the mean OCT thickness after Bevacizumab injection was observed among patients less than 60 years (P= 0.03), and male patients (p= 0.01). Examining patients by the reason of Bevacizumab injection, the mean OCT thickness was decreased after Bevacizumab injection for studied reasons and did show statistically significant differences among patients presented with DME, Neovascular glaucoma, Macular edema secondary to BRVO, and among those patients presented with Macular edema secondary to CRVO. Patients with best corrected visual acuity of ≥ 0.1 Decimal, showed significant decrease in the macular thickness after injection(p=0.04).
Table 3 presented the percent reduction in the macular thickness of OCT following injection of bevacizumab at three months follow up. Macular thickness after three months of injection was decreased. In the eyes of the studied patients with decreased macular thickness, there were 41 eyes (69.4%) with ≥10% decrease in macular thickness, 18 eyes (30.5%) with < 10% decrease in macular thickness.

Although, there were no statistically significant differences in the percent reduction, the higher proportion of eyes with > 10% macular thickness reduction was among patients aged ≤ 60 years (54.2%), male patients (37.2%), type II diabetics (52.5%), best corrected visual acuity of ≥ 0.1 (45.7%), non-hypertensive (42.3%), and those with DME (38.9%). The patient presented with neovacular glaucoma in this study showed more than 10% reduction in macular thickness after Bevacizumab injection.
Out of the studied 59 eyes of the studied patients, there were 38 eyes (64.4) with best corrected visual acuity of $\geq 0.1$ Decimal at baseline. After injection, the frequency of eyes with best corrected visual acuity was significantly increased ($p=0.01$) to reach 46 eyes (78%). Paired analyses of the above mentioned figure revealed that 9 (43%) out of studied 21 eyes with baseline visual acuity $<0.1$ were improved. Meanwhile only one eye (7.7%) of the studied 38 eyes with baseline visual acuity $\geq 0.1$ was deteriorated.

**Discussion**

The present case series follow up study included 59 eyes of the studied patients attending Ohoud Hospital, Madinah, Saudi Arabia; 35 eyes were diagnosed with DME, 9 with PDR, 5 with PDR and VH, 4 with DME and PDR, 2 with CNV secondary to ARMD, 2 with Macular edema secondary to CRVO, 1 with Macular edema secondary to BRVO and 1 with neovascular glaucoma. All cases were submitted to intravitreal injection of bevacizumab at eye center of Ohoud hospital, Madinah, Saudi Arabia during six-months study period from June to December 2015. Neither systemic nor ocular complications were seen in all studied patients during the study period. Absence of complications in this study was also noted in similar previous studies. On the other hand, a large uncontrolled clinical study included 4303 patients has reported cardiovascular and cerebrovascular complications in 18 patients, and bacterial endophthalmitis in 7.

*Significant*
In that study, however, the used inclusion and exclusion criteria were not so coherent that the potential risk of complications would not be prevented. In our and other similar studies, however, many patients with suggested risk of developing such complications were excluded, and all injection procedures were done under complete aseptic conditions.

The study findings revealed significant reduction in mean central macular thickness from 425.2 to 365.5 micrometers. Similar significant reduction in macular thickness was also reported in many studies. In one study, the central retinal thickness showed a considerable reduction from 498.9 at baseline to 370.4 micrometers at one month follow-up\(^2\). In another study carried out by Arevalo et al.\(^{17,18}\), the mean central macular thickness by OCT, among the studied 88 patients, was found to decrease from 387.0 at baseline to 275.7 at end of 16 weeks follow-up period. The mean decreases in central macular thickness after single intravitreal injection of 1.25mg of bevacizumab noticed after one month was about 61.4 ± 33.2 micrometers. In our study, the mean difference was very like that reported in the previous study. It was 59.7 ± 32.5.

In our study, stratified analysis by patients' characteristics were also performed and revealed significant reduction in the mean macular thickness after bevacizumab injection among patients less than 60 years, and male patients, and those with best corrected visual acuity at baseline ≥ 0.1. These findings coincide with that reported in many previous studies\(^{16-18}\), and confirm the accumulating literature that young age, male gender and best corrected visual acuity at baseline as the most important prognostic factors after intravitreal injection of bevacizumab. Stratified analysis by reason of injection showed statistically significant reduction in the mean macular thickness among patients presented with DME, Macular edema secondary to BRVO, Neovascular glaucoma and among those patients presented with Macular edema secondary to CRVO. These findings were also reported in previous similar studies.\(^{17,18}\)

The study findings found that 41 eyes showed ≥ 10% and 18 eyes showed < 10% decrease in macular thickness. Ateeq et al.\(^{20}\) in their study included 54 patients who were submitted to intravitreal injection of bevacizumab, 43 Eyes (79.6%) showed ≥ 10% decrease in macular thickness from pre-injection thickness, 10 Eyes (18.5%) showed < 10% decrease macular thickness post operatively after one month.

Macular thickness reduction, three months after bevacizumab, was analyzed in the present study by patients' diagnosis. More than ten percent reduction in macular thickness was found in 23 (38.9%) out of 59 patients with DME, 5 (8.4%) out of 9 patients with PDR, and 5 (8.4%) out of 5 patients presented with PDR and VR, and 4 (6.7%) out of 4 patients with DME and PDR. The use of bevacizumab with success in treatment of diabetic macular edema is very beneficial for diabetic patients. DME is one of the major complications, leading to irreversible visual loss among diabetic patients, and up to 10% of diabetics develop it during their lifetime.\(^{23}\) According to the Early Treatment Diabetic Retinopathy Study (ETDRS), focal laser photoagulation reduces the rate of visual loss by 50% among these patients. On the other hand, it is impossible to use complete macular grid laser in patients having media opacity like cataract, so there is a great need for an alternative or adjunctive treatment.\(^{20}\) The usefulness of intravitreal injection of bevacizumab in these patients may help to reduce visual loss in patients with DME.

The biologically plausibility of the effectiveness of intravitreal injection of bevacizumab in treatment of these patients could be explained by the etiologic factor implicated in development of macular edema. Vascular endothelial growth factor (VEGF), discovered in 1989, secreted by normal retinal pigment epithelial cells as result of hypoxia is known to be significantly elevated in diabetic eyes,\(^{25,26}\) particularly those eyes with proliferative diabetic retinopathy.\(^{27}\) It is also observed that eyes with heavy macular leakage to have significantly higher VEGF concentration compared to eyes with less leakage.\(^{28}\) Therefore, anti-VEGF treatments can be considered as an adjunctive treatment for DME.\(^{29}\) Bevacizumab is a monoclonal antibody that binds to all kinds of VEGF and thus inhibiting its adverse effects.\(^{3}\)

The second studied outcome parameter in this study was the visual acuity. At baseline, there were 38 eyes (64.4%) with best corrected visual acuity of ≥ 0.1 Decimal. Three months after intravitreal injection of bevacizumab, a significant improvement in patients' best corrected visual acuity by about 14% was detected in the studied eyes. Moreover, paired analyses have revealed that 9 (43%) out of studied 21 patients with baseline visual acuity < 0.1 Decimal were corrected, and only one eye (7.7%) of 38 eyes with baseline visual acuity ≥ 0.1 Decimal was deteriorated. Costa et al.\(^{30}\) have demonstrated significant dose-response changes in best corrected visual acuity at 3 months follow-up in their prospective, nonrandomized open-label study of 45 patients with ME and subfoveal CNV. The vision improved by +0.3 ETDRS line after a dose of 1.0 mg by +0.6 line after 1.5 mg, and by +1.0 line after 2.0 mg of intravitreal injection of bevacizumab. In a case report study, a 69 years old woman with DME underwent an intravitreal injection of bevacizumab at a dose of 2.5 mg in her eye. There has been an improvement of her visual acuity to 20/400 one
month, and 20/200 four months after injection. Another recent study has reported a highly significant improvement of visual acuity after intravitreal bevacizumab injection. The mean baseline acuity was 20/494 and the mean acuity at three months following injection was 20/295. Over the years, many studies have documented the highly effective role of anti-VEGF treatment in preserving visual acuity in most eyes with proliferative neovascularization and age-related macular denervation.

In conclusion, the study confirmed the usefulness and short-term efficacy of intravitreal injection of bevacizumab in patients with macular edema of different causes, particularly those with diabetes. Intravitreal bevacizumab injection was found to significantly reduce the central macular edema and to improve the visual acuity of the studied eyes. Selection of patients submitted to this procedure is mandatory to obtain these required positive results. Apart from its efficacy, intravitreal injection of bevacizumab has also appeared to be relatively safe in the short-term with no cases of systemic or ocular complications have been reported in this case series follow-up study.

According to our knowledge, this study is the first to assess short-term outcome of intravitreal injection bevacizumab injection in Madinah medical centers. Moreover, and unlike other similar studies, the present study has stratified all analyses concerning the studied outcome parameters by patients’ clinical and demographic characteristics. Though the above mentioned positive points, the nonrandomized nature of this study prevents any estimation of the long-term safety and/or efficacy of the studied procedure. However, the study findings are quite promising and suggest the need for further investigations with larger multicenter randomized studies.

Competing interests
The authors declare that there are no competing interests regarding the publication of this manuscript.

Limitations
The study was unable to score one-month OCT and there wasn’t further follow up after three months. The OCT results were limited in vitreous hemorrhage.

Conclusion
The study confirms the accumulating evidence of the usefulness and short-term efficacy of intravitreal injection of bevacizumab.

Further Work
The study suggests the need for further investigations with larger multicenter randomized studies and the need for increasing awareness about the importance of diabetes control and its impact in our region.

Acknowledgment
The authors would like to thank all patients participated in this study. The authors also acknowledge the help of all staff at eye center at Ohoud hospital especially Dr. Maram Alali.
